Chapter 1. Introduction

PHP_CompatInfo is a PHP library that parse any data source (file/folder/mixed) to find out the minimum version and extensions required for it to run. A CLI tool is available, giving results without to have to code a line of programmation.

The major version 2 is a full rewrites to PHP5, that used exceptions to raise errors, and an autoloader to dynamically load required classes.

If you want a PHP4 version compatible, you should consider to have a look on the branch 1.x solution hosted on PEAR repository :

- PEAR::PHP_CompatInfo [http://pear.php.net/package/PHP_CompatInfo] 1.9.0

I recommand to migrate to PHP5, because I don't gave anymore support for PHP4 versions

This manual documents the final stable version 2.3.0

Chapter 2. Features

- Parse a single file
- Parse a directory recursively or not
- Parse a list of files and/or directories
- Ability to give a list of extensions to ignore when calculating the version needed
- Ability to give a list of interfaces to ignore when calculating the version needed
- Ability to give a list of classes to ignore when calculating the version needed
- Ability to give a list of functions to ignore when calculating the version needed
- Ability to give a list of constants to ignore when calculating the version needed.
- Ability to give a list of files to ignore when calculating the version needed
- Ability to give a list of directories to ignore when calculating the version needed
- Ability to use a custom extensions list or by default only extensions loaded, to parse PHP code
- Event driven and listeners system to audit parsing process

Chapter 3. System Requirements

Required resources :

- PHP [<http://www.php.net>] 5.2.0 or newer
- Base [<http://ezcomponents.org/>] 1.8 or newer from *components.ez.no* PEAR channel
- ConsoleTools [<http://ezcomponents.org/>] 1.6.1 or newer from *components.ez.no* PEAR channel
- Console_CommandLine [http://pear.php.net/package/Console_CommandLine] 1.1.3 or newer from default PEAR channel
- PHP_Reflect [<http://bartlett.laurent-laville.org/>] 1.2.0 or newer from *Bartlett* PEAR channel
- tokenizer [<http://www.php.net/manual/en/book.tokenizer.php>] extension
- pcre [<http://www.php.net/manual/en/book.pcre.php>] extension
- SPL [<http://www.php.net/manual/en/book.spl.php>] extension
- DOM [<http://www.php.net/manual/en/book.dom.php>] extension
- libxml [<http://www.php.net/manual/en/book.libxml.php>] extension
- PHP_Timer [<http://pear.phpunit.de>] 1.0.0 or newer from *PHPUnit* PEAR channel

Optional resources :

- PEAR [<http://pear.php.net>] 1.9.0 or newer
- Net_Growl [http://pear.php.net/package/Net_Growl] 2.4.0 or newer
- PHPUnit [<http://pear.phpunit.de>] 3.5.0 or newer from *PHPUnit* PEAR channel
- an XSLT processor if you want to produce an xHTML report from a phpci xml report

Chapter 4. Installing PHP_CompatInfo

The current version of PHP_CompatInfo requires **PHP 5.2.0 or newer** to run. If you don't already have an up-to-date version of PHP installed it can be downloaded from the official PHP website <http://www.php.net/>.

4.1. Using PEAR installer

PHP_CompatInfo should be installed using the [PEAR Installer](<http://pear.php.net/>). This installer is the backbone of PEAR, which provides a distribution system for PHP packages, and is shipped with every release of PHP since version 4.3.0.

The PEAR channel (*bartlett.laurent-laville.org*) that is used to distribute PHP_CompatInfo needs to be registered with the local PEAR environment. Furthermore, components that PHP_CompatInfo depends upon is hosted on the eZ Components PEAR channel (*components.ez.no*), and on the PHPUnit PEAR channel (*pear.phpunit.de*).

```
$ pear channel-discover bartlett.laurent-laville.org
Adding Channel "bartlett.laurent-laville.org" succeeded
Discovery of channel "bartlett.laurent-laville.org" succeeded

$ pear channel-discover components.ez.no
Adding Channel "components.ez.no" succeeded
Discovery of channel "components.ez.no" succeeded

$ pear channel-discover pear.phpunit.de
Adding Channel "pear.phpunit.de" succeeded
Discovery of channel "pear.phpunit.de" succeeded
```

This has to be done only once. Now the PEAR Installer can be used to install packages from the Bartlett channel.

```
$ pear install bartlett/PHP_CompatInfo
downloading PHP_CompatInfo-2.2.0.tgz ...
Starting to download PHP_CompatInfo-2.2.0.tgz (754,629 bytes)
.....done: 754,629 bytes
install ok: channel://bartlett.laurent-laville.org/PHP_CompatInfo-2.2.0
```

After the installation you can find the PHP_CompatInfo source files inside your local PEAR directory.

Chapter 5. Getting Started

5.1. Introduction

PHP_CompatInfo branch 1.x is still compatible with PHP4, that is from an old age now (unmaintained). You can find it on PEAR main site on its project page [http://pear.php.net/package/PHP_CompatInfo].

PHP_CompatInfo branch 2.x is a full rewrite with PHP5. Since RC3 the PHP parser engine used is PHP_Reflect [<https://github.com/llaville/php-reflect>]. It's an improved version with "callbacks to what ever token you want" feature from basic concept version PHP_TokenStream [<https://github.com/sebastianbergmann/php-token-stream>].

5.1.1. What can PHP_CompatInfo do for you ?

Depending of server API you will use, PHP_CompatInfo main goal is to give you the minimum and maximum PHP versions, a script or a list of scripts (sources), are required to run code.

But PHP_CompatInfo (alias `phpci`), may also provides on CLI (with the `phpci` command) :

- Reference informations (MIN and MAX PHP versions) about one or more extensions :
 - list all classes
 - list all interfaces
 - list all functions
 - list all constants
- Print multiple reports group by scanned files or components
 - **summary** : usage summary of each extension, interface, class, function, constant used by your sources code
 - **source** : lines code count summary with or without source code
 - **xml** : export result to a XML format easy to transform to xHTML or other format
 - **token** : language PHP5 special features such as try/catch/throw exception, etc
 - **extension** : usage, minimum php version and origin of each extension used by your sources code
 - **namespace** : usage, minimum php version and origin of each namespace used by your sources code
 - **trait** : usage, minimum php version and origin of each trait used by your sources code
 - **interface** : usage, minimum php version and origin of each interface used by your sources code
 - **class** : usage, minimum php version and origin of each class used by your sources code

- **function** : usage, minimum php version and origin of each function used by your sources code
- **constant** : usage, minimum php version and origin of each constant used by your sources code
- **global** : usage, minimum php version and origin of each global variable used by your sources code

5.2. A simple tutorial

5.2.1. Parse a single file with default options

To parse a file with the PHP5 known references of your extensions loaded, you have just to specify the file's location.

API example.

```
<?php
require_once 'Bartlett/PHP/CompatInfo.php';

$source = '/path/to/myFile.php';

try {
    $phpci = new PHP_CompatInfo();
    $phpci->parse($source);

    $allResultsAtOnce = $phpci->toArray();
} catch (PHP_CompatInfo_Exception $e) {
    die ('PHP_CompatInfo Exception : ' . $e->getMessage() . PHP_EOL);
}
```

phpci tool example. From your PEAR *bin_dir* directory run this command

```
$ phpci --no-configuration print --reference PHP5 --report summary /path/to/myFile.php
```

It won't use the default XML configuration file `phpcompatinfo.xml` or `phpcompatinfo.xml.dist` If you are sure of XML configuration settings, remove the `--no-configuration` option.

Will print out a summary report like this one

```
PHP COMPAT INFO REPORT SUMMARY
-----
FILES                                EXTENSIONS INTERFACES CLASSES FUNCTIONS CONSTANTS
-----
BASE: /path/to
-----
DIR.:
myFile.php                            5              3             11            27             4
-----
A TOTAL OF
  5 EXTENSION(S) 3 INTERFACE(S) 11 CLASSE(S) 27 FUNCTION(S) 4 CONSTANT(S)
WERE FOUND IN 1 FILE(S)
WITH CONDITIONAL CODE LEVEL 32
REQUIRED PHP 5.1.3 (MIN)
```

```
Time: 2 seconds, Memory: 8.50Mb
```

5.2.2. Parse a directory with default options

If you wish to parse an entire directory, you can specify the directory location instead of a file.

API example.

```
<?php
require_once 'Bartlett/PHP/CompatInfo.php';

$source = '/path/to/myFolder';

try {
    $phpci = new PHP_CompatInfo();
    $phpci->parse($source);

    $allResultsAtOnce = $phpci->toArray();
} catch (PHP_CompatInfo_Exception $e) {
    die ('PHP_CompatInfo Exception : ' . $e->getMessage() . PHP_EOL);
}
```

phpci tool example. From your PEAR *bin_dir* directory and the default XML configuration file *phpcompatinfo.xml.dist* installed into PEAR *cfg_dir*/PHP_CompatInfo.

```
$ phpci print /path/to/myFolder
```

Will print out the summary report

```
PHP COMPAT INFO REPORT SUMMARY
-----
FILES                                EXTENSIONS INTERFACES CLASSES FUNCTIONS CONSTANTS
-----
BASE: /path/to/myFolder
-----
DIR.:
Cache.php                            3              0              2              4              3
CLI.php                              3              0              8             16             6
Configuration.php                    3              0              5             10             3
Exception.php                        1              0              2              0              0
Reference.php                         1              1              0              0              1
Report.php                           2              0              2             11             3
TokenParser.php                      2              0             14              9              3
TokenStream.php                      4              0              3             17             3

```

Chapter 6. API basic usage

6.1. Default options

Whether you use the CLI version with the *phpci* command, or directly API functions, `PHP_CompatInfo` has some default options you should learn if you want to understand results provided.

Depending on SAPI you will use, source of settings is different.

Default options printed below, may be changed by the `$options` parameter of `PHP_CompatInfo` class constructor.

Option	Default	Description
<code>recursive</code>	<code>false</code>	scan recursive subdirectories or just local files
<code>reference</code>	<code>PHP5</code>	data dictionary reference (all PHP4 and PHP5 informations)
<code>referencePlugins</code>	<code>PHP4[...], PHP5[...]</code>	adapters to connect to data dictionaries reference
<code>verbose</code>	<code>false</code>	output more information
<code>fileExtensions</code>	<code>[php, inc, phtml]</code>	list of file extensions to scan
<code>cacheDriver</code>	<code>file</code>	cache results to improve speed of next iteration
<code>cacheOptions</code>	<code>[save_path => /tmp]</code>	options specific to cache driver used
<code>listeners</code>	<code>[]</code>	none

6.2. Scanning Files and Folders

The simplest way of using `PHP_CompatInfo` is to provide the location of a file or folder for `PHP_CompatInfo` to scan. If a folder is provided, `PHP_CompatInfo` will scan all files it finds in that local folder.

If you want sub-folders scanned, use the `recursive` option.

Example: do not use cache files, but parse directory recursively.

```
<?php
require_once 'Bartlett/PHP/CompatInfo.php';

$source = '/path/to/myFolder';
$options = array(
    'cacheDriver' => 'null',
    'recursive'   => true
);
```

```

try {
    $phpci = new PHP_CompatInfo($options);
    $phpci->parse($source);

    $allResultsAtOnce = $phpci->toArray();
} catch (PHP_CompatInfo_Exception $e) {
    die ('PHP_CompatInfo Exception : ' . $e->getMessage() . PHP_EOL);
}

```

6.3. Specifying a Reference

PHP_CompatInfo can have multiple references installed to allow a single installation to be used with multiple platform. When scanning PHP code, PHP_CompatInfo can be told which reference to use. This is done using the `reference` option.

Example: specify a PHP4 reference to parse only PHP 4 sources code.

```

<?php
require_once 'Bartlett/PHP/CompatInfo.php';

$source = '/path/to/myFolder';
$options = array(
    'reference' => 'PHP4',
);

try {
    $phpci = new PHP_CompatInfo($options);
    $phpci->parse($source);

    $allResultsAtOnce = $phpci->toArray();
} catch (PHP_CompatInfo_Exception $e) {
    die ('PHP_CompatInfo Exception : ' . $e->getMessage() . PHP_EOL);
}

```

If you want to use your own reference, you should have (of course) to write it, but you must also tell where it is.

Example: replaces default references provided in standard distribution.

```

<?php
require_once 'Bartlett/PHP/CompatInfo.php';

$source = '/path/to/myFolder';
$options = array(
    'reference' => 'PHP5',
    'referencePlugins' => array(
        'PHP5' => array(
            'class' => 'myRefClass',
            'file' => '/path/to/file/hosting/myRefClass.php',
            'args' => array()
        ),
    ),
);

```

```
try {
    $phpci = new PHP_CompatInfo($options);
    $phpci->parse($source);

    $allResultsAtOnce = $phpci->toArray();
} catch (PHP_CompatInfo_Exception $e) {
    die ('PHP_CompatInfo Exception : ' . $e->getMessage() . PHP_EOL);
}
```

Chapter 7. Using PHP_CompatInfo from the command line

7.1. Differences to other SAPI

Remarkable differences of the CLI SAPI compared to other SAPI:

- gets responses in a seconde without code line to write
- printing components report
- printing references informations report
- configurable thru an easy to read XML file

7.2. Options

The list of command line options provided by the *phpci* command can be queried anytime by running *phpci* with the *-h* or *--help* switches.

```
PHPCompatInfo (cli) by Laurent Laville.
```

```
Usage:
```

```
  phpci [options]
  phpci [options] <command> [options] [args]
```

```
Options:
```

```
--configuration=xmlFile      Read configuration from XML file
--no-configuration           Ignore default configuration file
                              (phpcompatinfo.xml)
-d iniSet, --ini-set=iniSet  Sets a php.ini directive value
-v, --verbose                 Output more verbose information
-h, --help                   show this help message and exit
--version                     show the program version and exit
```

```
Commands:
```

```
print          Print a report of data source parsed.
list-references List all extensions supported.
list           List all "elements" referenced in the data base.
list-extensions List all extensions referenced in the data base.
list-interfaces List all interfaces referenced in the data base.
list-classes   List all classes referenced in the data base.
list-functions List all functions referenced in the data base.
list-constants List all constants referenced in the data base.
```

Short Option	Long Option	Description
	--configuration	Specify a custom XML file (which does not need to be named phpcompatinfo.xml or located into PEAR cfg_dir)

Short Option	Long Option	Description
	--no-configuration	Ignore default configuration files <code>phpcompatinfo.xml</code> or <code>phpcompatinfo.xml.dist</code>
-d	--ini-set	This option allows you to set a custom value for any of the configuration directives allowed in <code>php.ini</code> . Example: <code>-d memory_limit=256M</code>
-v	--verbose	Sets the verbose level to print more informations
-h	--help	With this option, you can get information about the actual list of command line options and some one line descriptions about what they do.
	--version	Prints the version of PHP_CompatInfo and exits.

Unless you tell it to ignore the XML configuration file, default options are sets by the `phpcompatinfo.xml.dist` file if found into the PEAR `cfg_dir \PHP_CompatInfo` directory

```
<?xml version="1.0" encoding="utf-8" ?>
<phpcompatinfo
  reference="PHP5"
  report="summary"
  reportFileAppend="false"
  cacheDriver="file"
  recursive="false"
  fileExtensions="php, inc, phtml"
  consoleProgress="true"
  verbose="false"
  >
  <!-- ... -->
</phpcompatinfo>
```

7.3. Commands

They are two categories of command:

- printing scanned sources code results
- listing database references extensions informations

7.3.1. print command

This command allow to print results of scanned sources code. If you forget options, enter command below.

```
$ phpci print --help
```

That will show you this help screen:

```
Print a report of data source parsed.
```

```
Usage:
```

Using PHP_CompatInfo from the command line

```
phpci [options] print [options] <sourcePath>
```

Options:

<code>--reference=reference</code>	The name of the reference to use
<code>--report=report</code>	Type of report
<code>--report-file=reportFile</code>	Write the report to the specified file path
<code>--exclude-pattern=excludeID</code>	Exclude components from list referenced by ID provided
<code>-R, --recursive</code>	Includes the contents of subdirectories
<code>--file-extensions=fileExtensions</code>	A comma separated list of file extensions to check
<code>--help-reference</code>	List of reference available
<code>--help-report</code>	List of report available
<code>-h, --help</code>	show this help message and exit

Arguments:

`sourcePath` The data source to scan (file or directory).

Short Option	Long Option	Description
	<code>--reference</code>	This option tells what reference dictionary to use. May be either one providing by the package distribution or your own.
	<code>--report</code>	Specify what kind of report to print. See <code>--help-report</code> for full list.
	<code>--report-file</code>	This option identify the file where results will be written.
	<code>--exclude-pattern</code>	Identify a <code><exclude></code> element in the XML configuration file, that define what elements to exclude from scope.
<code>-R</code>	<code>--recursive</code>	This option allow to parse directories recursively.
	<code>--file-extensions</code>	When parsing directory, specify what file to scan.
	<code>--help-reference</code>	Remember you what are reference dictionary available in default distribution.
	<code>--help-report</code>	Remember you what are reports available in default distribution.
<code>-h</code>	<code>--help</code>	With this option, you can get information about the actual list of command line options.

You can give one or more report at the same time.

Example: Printing only summary report.

```
$ phpci print --report summary /path/to/source
```

Example: Printing both summary, extension, interface, class, function, and constant reports.

```
$ phpci print --report summary extension interface class function constant /path/to/source
```

Example: Printing both function and constant reports.

```
$ phpci print --report function --report constant /path/to/source
```

7.3.2. list-references command

This command allow to print the list of documented extensions available with your version of PHP_CompatInfo, and specify those which are currently loaded (**L** in front or their names)

If you forget options, enter command below.

```
$ phpci list-references --help
```

That will show you this help screen:

```
List all extensions supported.
```

```
Usage:
```

```
  phpci [options] list-references [options]
```

```
Options:
```

```
  --report-file=reportFile  Write the report to the specified file path  
  -h, --help                show this help message and exit
```

Short Option	Long Option	Description
	--report-file	This option identify the file where results will be written.
-h	--help	With this option, you can get information about the actual list of command line options.

Example.

```
$ phpci list-references
```

```

7.3.3. list command

This command allow to combine one or more list-* command.

results may be huge

If you forget options, enter command below.

```
$ phpci list --help
```

That will show you this help screen:

```
List all "elements" referenced in the data base.

Usage:
  phpci [options] list [options] <element...>

Options:
  --reference=reference      The name of the reference to use
  --report-file=reportFile  Write the report to the specified file path
  --help-reference          List of reference available
  -h, --help                show this help message and exit

Arguments:
  element  May be either "extensions", "interfaces", "classes", "functions"
           or "constants"
```

Short Option	Long Option	Description
	--reference	This option tells what reference dictionary to use. May be either one providing by the package distribution or your own.
	--report-file	This option identify the file where results will be written.
	--help-reference	Remember you what are reference dictionary available in default distribution.
-h	--help	With this option, you can get information about the actual list of command line options.

Example: list both interfaces and classes of all extensions supported by PHP_Compatinfo.

```
$ phpci list interfaces classes
```

```
-----
PHP COMPAT INFO INTERFACES REFERENCE

7.3.4. list-extensions command

This command allow to print the list of documented extensions available with your version of PHP_CompatInfo, and loaded on your platform.

If you forget options, enter command below.

```
$ phpci list-extensions --help
```

That will show you this help screen:

```
List all extensions referenced in the data base.
```

```
Usage:
```

```
  phpci [options] list-extensions [options] <extension>
```

```
Options:
```

```
--reference=reference      The name of the reference to use  
--report-file=reportFile  Write the report to the specified file path  
--help-reference          List of reference available  
-h, --help                show this help message and exit
```

```
Arguments:
```

```
  extension (optional) Limit output only to this extension
```

Using PHP_CompatInfo

```

Chapter 8. The XML Configuration File

8.1. Main options

The attributes of the `<phpcompatinfo>` element can be used to configure PHP_CompatInfo's core functionality.

```
<?xml version="1.0" encoding="utf-8" ?>
<phpcompatinfo
  reference="PHP5"
  report="summary"
  reportFileAppend="false"
  cacheDriver="file"
  recursive="false"
  fileExtensions="php, inc, phtml"
  consoleProgress="true"
  verbose="false"
>

<!-- ... -->
</phpcompatinfo>
```

The XML configuration above corresponds to the default behaviour of the `phpcli` tool.

reference

Data dictionary reference name. Defaults to PHP5 for all PHP4 and PHP5 components depending of your extensions loaded.

report

Kind of report to produces. May be either *summary*, *source*, *xml*, *token*, *extension*, *namespace*, *interface*, *class*, *function*, *constant*, *global*

reportFile

File that will contains the console results. Defaults output to console only.

reportFileAppend

If you used the *reportFile* option, shall we replace its contents or not.

cacheDriver

Either you use the *file* system cache, or don't want to cache results *null*.

recursive

If you want to explore sub-directories of data source provided (*true*) or not (*false*).

fileExtensions

A comma separated list of file extensions to parse.

consoleProgress

Display (*true*) or not (*false*) a progress bar while scanning data source.

verbose

Output more verbose information.

8.2. Cache options

```
<?xml version="1.0" encoding="utf-8" ?>
<phpcompatinfo
  ... >

  <cache id="file">
    <options>
      <save_path>/tmp</save_path>
      <gc_probability>1</gc_probability>
      <gc_maxlifetime>86400</gc_maxlifetime>
    </options>
  </cache>

</phpcompatinfo>
```

The `<cache>` element and its `<options>` child can be used to improve speed of parsing.

Default behavior will cache parsing results in a serialized data format on files backend of your local file system.

save_path

this is the path where the files (`pci_<md5Hash>`) are created.

gc_probability

`gc_probability` is used to manage probability that the gc (garbage collection) routine is started. Defaults to 1

gc_maxlifetime

`gc_maxlifetime` specifies the number of seconds after which data will be seen as *garbage* and potentially cleaned up. Garbage collection may occur after parsing data source. Defaults to 86400 (1 day)

To clean the cache, set the probability (`gc_probability`) to 100, and reduce the life time (`gc_maxlifetime`) to 1 second.

References

```
<?xml version="1.0" encoding="utf-8" ?>
<phpcompatinfo
  ... >

  <references>
    <reference name="Core" />
    <reference name="standard" />
  </references>

</phpcompatinfo>
```

The `<references>` element and its `<reference>` children can be used to specify what extension you want to detect and none others.

Default behaviour will auto-detect all your extensions loaded [<http://www.php.net/manual/en/function.extension-loaded.php>].

8.3. Setting PHP INI settings

```
<?xml version="1.0" encoding="utf-8" ?>
<phpcompatinfo
  ... >

  <php>
    <ini name="memory_limit" value="140M" />
    <ini name="short_open_tag" />
    <ini name="zend.zel_compatibility_mode" value="false" />
  </php>

</phpcompatinfo>
```

The `<php>` element and its `<ini>` children can be used to configure PHP settings.

With **phpci** console tool, you can also sets a PHP directive value with `--ini-set` switch.

Examples.

```
$ phpci --ini-set memory_limit=140M print /path/to/mySource

// both give same results
$ phpci --ini-set short_open_tag print /path/to/mySource
$ phpci --ini-set short_open_tag=true print /path/to/mySource
```

8.4. Excluding Files or Elements from parsing

```
<?xml version="1.0" encoding="utf-8" ?>
<phpcompatinfo
  ... >

  <excludes>
    <exclude id="demo">
      <directory name=".*\Zend\.*" />
      <file name=".*\.php5" />
      <extension name="xdebug" />
      <interface name="SplSubject" />
      <class name=".*Compat.*" />
      <function name="ereg.*" />
      <function name="debug_print_backtrace" />
      <constant name="T_USE" />
    </exclude>
  </excludes>

</phpcompatinfo>
```

The `<excludes>` element and its children can be used to configure what element to ignore from parsing. It may be a list of folders (`<directory>`), files, extensions, interfaces, classes, functions or constants.

Default behaviour ignore nothing.

With **phpci** console tool, you can invoke it with the following switch:

```
--exclude-pattern <id>
```

Example.

```
$ phpci --exclude-pattern demo print /path/to/mySource
```

8.5. Scan Listeners

```
<?xml version="1.0" encoding="utf-8" ?>
<phpcompatinfo
  ... >

  <listeners>
    <listener class="className" file="/path/to/filename">
      <arguments>
        </arguments>
    </listener>
    <listener class="PHP_CompatInfo_Listener_File" />
    <listener class="PHP_CompatInfo_Listener_Growl">
      <arguments>
        <string>PHP_CompatInfo</string>
        <array>
          <element key="info">
            <array>
              <element key="display">
                <string>Information</string>
              </element>
              <element key="enabled">
                <boolean>true</boolean>
              </element>
            </array>
          </element>
          <element key="warning">
            <array>
              <element key="enabled">
                <boolean>true</boolean>
              </element>
            </array>
          </element>
        </array>
        <string>mamasam</string>
        <array>
          <element key="host">
            <string>192.168.1.2</string>
          </element>
          <element key="timeout">
            <integer>10</integer>
          </element>
          <element key="debug">
            <string>/path/to/logFile</string>
          </element>
        </array>
      </arguments>
    </listener>
  </listeners>
```

```
</phpcompatinfo>
```

The `<listeners>` element and its `<listener>` children can be used to attach additional observers to the parses process.

The **phpci** console tool know in standard distribution the **File** and **Growl** listeners.

Please refer to PEAR::Net_Growl [<http://growl.laurent-laville.org/>] package for configuration options.

You may add your own observer. To do so, specify the class name (*class* attribute of `<listener>` element) hosted by a file (*file* attribute of the same `<listener>` element) that implement the SplObserver [<http://www.php.net/manual/en/class.spobserver.php>] interface.

8.6. Plugins

```
<?xml version="1.0" encoding="utf-8" ?>
<phpcompatinfo
  ... >

  <plugins>
    <reference name="MyReference"
      class="PEAR_CompatInfo"
      file="/path/to/PEARCompatInfo.php">
      <arguments>
      </arguments>
    </reference>
  </plugins>

</phpcompatinfo>
```

The `<plugins>` element and its `<reference>` children can be used to specify your own data dictionary references. Usefull when an extension data dictionary is not available in the standard distribution.

Default behaviour is to load all PHP4 and PHP5 known elements referenced by the `PHP_CompatInfo_Reference_PHP5` class. See the *reference* attribute of `<phpcompatinfo>` element.

You may add your own plugin. To do so, specify the class name (*class* attribute of `<reference>` element) hosted by a file (*file* attribute of the same `<reference>` element). Your class should inherit from `PHP_CompatInfo_Reference_PluginsAbstract` abstract class that implement the `PHP_CompatInfo_Reference` interface.

With **phpci** console tool, you can invoke it with the following switch:

```
--reference <name>
```

Example.

```
$ phpci --reference MyReference print /path/to/mySource
```

Appendix A. Postprocessing the report file with XSLT

A.1. Main options

There are several XSLT scripts which can be used to transform the XML report into some nice html pages.

To do this, make sure you've first generate the XML report, i.e:

```
$ phpcli print --report xml --report-file <report.xml> <dataSource>
```

And then use the xslt processor to transform the XML to a beautiful XHTML page.

```
$ xsltproc -o <output_page.html> summary.xsl <report.xml>
```
